

AI or Human: Who Do We Prefer to Correct Us?

M. Doornbos, T. Schuur, P. Sipass

1 Introduction

As AI learning tools are becoming more common, it is important to examine how we interact with AI agents who are teaching us. This experiment explores whether people prefer to be corrected by a human or AI agent when they are solving spatial IQ puzzles. The presence of an AI agent was faked by viewing a live video feed of the participants and correcting them from a distance, ensuring that participants believed it was an AI agent pointing out their mistakes. Data was collected by means of a post-task questionnaire.

2 Methodology

Participants were asked to solve 3 spatial logic IQ puzzles in a row. The first round was a control test with no correction. During the second round one group (A) would be corrected by the “AI” and one group (B) would be corrected by a human. In the final round, the group A and B would switch so that everyone was corrected by a human and an “AI”. Human correction was done by standing next to the participant and playing a sound file of a woman saying “wrong” whenever the participant made a mistake.

3 Results

While most participants (6) preferred a human agent, an insignificant part of the participants (3) rather had the “AI” agent correcting their mistakes. Similarly, those who preferred being corrected by a human found being corrected by the “AI” agent more stressful. The opposite is true for those who preferred the “AI” agent. There was no noticeable difference in data between group A and group B.

Ratings (scale of 1 to 10) for how stressful it was to be corrected by a human versus an AI.

Ratings (scale of 1 to 10) for how pleasant it was to be corrected by a human versus an AI.

4 Conclusion

We found no clear difference in stress or enjoyment levels between human and AI correction. On average, human correction was rated slightly more positively. However, individual responses varied, with some participants having specific comments on how they found the “AI” agent's voice annoying, or how they felt more judged when being corrected by a human agent. Furthermore, age may also play a role in how correction is perceived and processed [1]. Future research with more participants could help clarify these effects and uncover patterns across age groups.
